## Basics

```
n treatment factors A,B,C,. . ,H,J,K,. . .
- each with levels 0 and 1 from GF(2),
and addition modulo 2
(used here)
- or each with levels -1 and +1, and multiplication
(closer to conventional industrial statistics,
automatically yields nice model matrices for estimation)
```

## A full factorial has all $2^{n}$ conceivable level combinations.

```
A full model has \(2^{n}\) effects (1 constant, \(n\) main effects, \(\binom{n}{2} 2\)-factor interactions, ...).
```

Full model model matrix ( $\mathrm{n}=4$ factors)

## Blocking full factorials

Full factorial
2-level designs
Blocking full factorials

Regular fractional factorial 2-level designs

Clear
two-factor interactions

Back matter

## Basics

Purpose control for variation in the experimental material
Blocking $\quad N=2^{n}$ runs can be assigned to $N / 2^{q}=2^{n-q}$ blocks of size $2^{q}$
has $2^{n-q}$ levels (needs $2^{n-q}-1 \mathrm{df}$ )

## Assumptions

- block effect active, but not of interest
- block factors do not interact with treatment factors
in line with Godolphin, look at only a single block factor

## Blocking a full factorial in $n$ factors

Approach of FrF2
pick $n-q$ independent effect columns for generating the levels of the block factor
e.g. for $n=4$ and $q=2: b_{1}=\mathrm{ABC}$ and $b_{2}=\mathrm{ABD}$

- the remaining dfs of the block factor are implied by the generating columns e.g. $b_{3}=\left(b_{1}+b_{2}\right) \bmod 2=(A B C+A B D) \bmod 2=C D$

Approach in • Godolphin (X approach)
pick $q$ independent rows without all-zero columns that generate a group of size $2^{q}$,
which is the principal block (pb)
take the other blocks as the cosets of the principal block

## $X$ approach in detail

$q \times n$ matrix $\mathbf{X}$, rank $q$, no all-zero columns
Example continued

$$
\mathbf{X}=\underset{\mathrm{acd}}{\mathrm{bcd}}\left(\begin{array}{cccc}
\mathrm{A} & \mathrm{~B} & \mathrm{C} & \mathrm{D} \\
0 & 1 & 1 & 1 \\
1 & 0 & 1 & 1
\end{array}\right) \Longrightarrow \mathrm{pb}=\underset{\substack{\mathrm{acd} \\
\mathrm{ab}}}{\substack{(1)}}\left(\begin{array}{cccc}
A & B & C & D \\
0 & 0 & 0 & 0 \\
0 & 1 & 1 & 1 \\
1 & 0 & 1 & 1 \\
1 & 1 & 0 & 0
\end{array}\right)
$$

Further blocks are the cosets:

$$
\begin{aligned}
& \mathrm{pb}+\mathrm{a}: \mathrm{a}, \mathrm{abcd}, \mathrm{~cd}, \mathrm{~b} \\
& \mathrm{pb}+\mathrm{c}: \mathrm{c}, \mathrm{bd}, \mathrm{ad}, \mathrm{abc} \\
& \mathrm{pb}+\mathrm{d}: \mathrm{d}, \mathrm{bc}, \mathrm{ac}, \mathrm{abd}
\end{aligned}
$$

## Example: Blocking a full factorial

The four rows of the principal block for two different blockings of the full factorial in factors A, B, C and D.
Bold face: the $2 \times 4 \mathrm{X}$ matrix for the blocking.
The table shows columns for all factorial effects.

|  | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Regular fractions (unblocked)

A regular fraction ( $2^{p}$ th fraction of the $2^{n}$ run full factorial) has $N=2^{k}=2^{n-p}=2^{n} / 2^{p}$ level combinations.

## Example

$$
\begin{aligned}
& n=6, p=2, k=n-p=4 \\
& N=16 \text { runs, design matrix } 16 \times 6, \text { model matrix } 16 \times 16
\end{aligned}
$$

- A regular fraction is obtainable from a full factorial in $k=n-p$ basic factors by $p>0$ defining contrasts, which declare the effects from the full model in the basic factors that define the levels of $p$ additional factors.

## Example: $\mathrm{E}=\mathrm{ABC}, \mathrm{F}=\mathrm{ABD}$

- Equivalently, there is a group theoretic creation approach (not discussed).

## Regular fractions

Fractionating counfounds the $2^{n}$ effects of the full model in groups of $2^{p}$ effects that cannot be separated.

Example
Column headers for the model matrix
show the confounding pattern.

| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathbf{l}$ | $\mathbf{A}$ | $\mathbf{B}$ | $\mathbf{A B}$ | $\mathbf{C}$ | $\mathbf{A C}$ | BC | ABC |
| ABCE | BCE | ACE | CE | ABE | BE | AE | E |

## Group of words and resolution

## Matrix notation for fractionating

Matrix notation for defining contrasts $E=A B C$ and $F=A B D$ :

$$
\mathbf{Z}=\begin{gathered}
\mathrm{E} \\
\mathrm{~F}
\end{gathered}\left(\begin{array}{cccc}
\mathrm{A} & \mathrm{~B} & \mathrm{C} & \mathrm{D} \\
1 & 1 & 1 & 0 \\
1 & 1 & 0 & 1
\end{array}\right)
$$

$\mathbf{Z}$ is used in Godolphin's blocking approach for fractional factorials.

## Blocking a fractional factorial

$n$ factors, $2^{k}=2^{n-p}$ runs, $p>0, k=n-p$ basic factors $q \times n$ matrix $\mathbf{X}$ needed for creating $2^{q} \times n$ principal block

Change versus full factorial

Approach

Example: Previous $X$ as
$X_{1}$ with $E=A B C$ and $\mathrm{F}=\mathrm{ABD}$

Problem

Solution
cannot freely choose all $n$ columns of $\mathbf{X}$, $k$ columns for the basic factors determine the entire $\mathbf{X}$

Choose $q \times k$ matrix $\mathbf{X}_{1}$, calculate $q \times p$ matrix $\mathbf{X}_{I I}=\mathbf{X}_{1} \mathbf{Z}^{\top}$, and use $\mathbf{X}=\left(\mathbf{X}_{1}: \mathbf{X}_{\text {II }}\right)$.

$$
\mathbf{X}_{I}=\left(\begin{array}{llll}
0 & 1 & 1 & 1 \\
1 & 0 & 1 & 1
\end{array}\right) \quad \text { and } \quad \mathbf{X}_{I I}=\mathbf{X}_{\mathbf{I}} \mathbf{Z}^{\top}=\left(\begin{array}{ll}
0 & 0 \\
0 & 0
\end{array}\right)
$$

$\mathrm{X}_{\text {II }}$ may contain all-zero column(s)
$\rightarrow$ treatment main effect(s) would be confounded with the block effect.
brute force search over all $\mathbf{X}_{\text {I }}$ for permissible blockings

## Example: Blocking a fractional factorial

The four rows of the principal block for two different blockings of the fractional factorial with basic factors $A, B, C$ and $D$ and added factors $E=A B C$ and $F=A B D$.

Bold face: the $2 \times 6 \mathbf{X}$ matrix for the blocking: $\mathbf{X}=\left(\mathbf{X}_{I}: \mathbf{X}_{\|}\right)$

| 0 | $\mathbf{1}$ | $\mathbf{2}$ | 3 | $\mathbf{4}$ | 5 | 6 | 7 | $\mathbf{8}$ | 9 | 10 | 11 | 12 | 13 | 14 | 15 |

## Clear two-factor interactions

Full factorial
2-level designs
Blocking full factorials

Regular fractional factorial 2-level designs

Clear two-factor interactions

Back matter

## Clear 2fis

are not confounded with main effects or other 2 fis, and neither with the block factor

## Situation

- other 2 fis may not be of interest, but must not be assumed negligible
- higher order interactions can be neglected

Goal fractionate and/or block such that required 2 fis are clear

## Sources

- Grömping (2012) provided an algorithm for unblocked fractions
- Godolphin (2021) provided the relation of the $\mathbf{X}$ approach to clear 2fis and a paper-catalogue for blocked fractions
- Grömping (2021) provided an automated algorithm for blocked fractions with clear 2fis, based on both Grömping (2012) and Godolphin (2021)

## Clear interactions graphs (CIGs)

- each factor is the vertex of a graph
- there is an edge for each clear 2 fi

Design CIG of best fraction for six factors

## Using CIGs

left: requirement CIG, right: design CIG (7-2.1)
Task allocate treatment factors such that required 2 fis are clear
Example allocate treatment factors $A$ to $G$ to design factors 1 to 7

- B, C and E must be on 4,5 and 7
$\bullet$
FrF2: subgraph isomorphism checks automate the allocation

## $X$ approach for full factorial revisited

$\chi_{q}$

Important
Rule
Example:
Blocking 1

$$
\mathbf{X}=\left(\begin{array}{llll}
0 & 1 & 1 & 1 \\
1 & 0 & 1 & 1
\end{array}\right)
$$

CD is confounded with blocks, the other five 2 fis are clear.

Approach

- For a specific 2 fi to be clear, assign different columns to its two factors.
- For a large number of clear 2fis, use the columns from $\chi_{q}$ in the highest possible balance $\rightarrow$ see "profiles" below.

## Example: X approach for full factorial

The four rows of the principal block for two different blockings of the full factorial in factors A, B, C and D.
Bold face: the $2 \times 4 \mathbf{X}$ matrix for the blocking.
Highlighted: 2fis confounded with blocks

| 0 | 1 | 1 | 0 | 1 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 0 | 1 | 1 | 0 |

## X approach for full factorial in graphs

- $\mathbf{X}$ partitions the design factors into $2^{q}-1$ sets, whose 2 fis are confounded within sets (no edges), but not between sets (edges).
- The design CIG is a full $2^{q}$ - 1-partite graph for the partitions, and thus $2^{q}-1$ colourable.
- The sizes of the partition sets can be written in a profile, e.g. $\langle 5,5,3>$ or $\langle 9,3,1\rangle$.

## Four 3-partite graphs for 13 factors

Profile < 7,5,1>
47 clear 2 fis

Profile <7,3,3>
51 clear 2 fis

Profile <9,3,1>

## X approach for full factorial in graphs

A requirement CIG can be accommodated in blocks of size $2^{q}$, if it is $2^{q}-1$-colourable.

Profile <3,3,1>

Requirement CIG that can be accommodated in blocks of size 4

## X approach for fractional factorial revisited

For a given $\mathbf{X}$, the rule for confounding of 2fis with the block effect remains valid.

Resolution V If a suitable $\mathbf{X}$ has been found, the CIG coincides with that of a full factorial fraction

Resolution IV fraction

2 fis may already be confounded with other 2 fis in the unblocked fraction.
The CIG from blocking an unblocked fraction by $\mathbf{X}$ is the intersection of the CIG of the unblocked fraction
with the CIG from blocking a full factorial by the same $\mathbf{X}$. Deciding on a good $\mathbf{X}$ is thus more complicated.

## Godolphin catalogues (blocks of size $2^{2}=4$ )

## Resolution V

Resolution IV
paper catalogues of partitions for selected numbers of factors, in some cases with additional information of additional 2 fis that are confounded already in the unblocked fraction, for a few combinations of $n, N, q$ and profiles

FrF2
$\square$ allows R-savvy users to extend the situations for which blockings with estimable 2 fis can be found (e.g. also extending Godolphin's paper catalogues)

## Algorithmic implementation in FrF2

Catalogue Unblocked fractions sorted from better to worse WLP, with design CIGs

## Algorithm

loop through unblocked fractions, until one can accommodate the requirement CIG (algorithm of Grömping 2012)
search for a suitable $q \times n$ matrix $\mathbf{X}$ for blocking that fraction without sacrificing required 2 fis (see next slide)
if one is found: record number of clear 2fis if not maximum conceivable: try next $\mathbf{X}$ matrix
4 if $\mathbf{X}$ matrices have been found, use the one that keeps the largest number of 2fis clear;
otherwise, manually restart the first step after discarding the unusable unblocked fraction

## Search algorithm for a suitable $X$

Crucial for speed

It does not matter which column from $\mathcal{X}_{q}$ is used for which colour.

Denote $\mathcal{X}_{q}=\left\{\xi_{1}, \ldots, \xi_{2^{q}-1}\right\}$, i.e. assign an order to the elements. Then choose the columns of $\mathbf{X}_{I}$ as follows:

- Fix the first column as $\xi_{1}$ (one choice).
- If $2^{q}-1 \geq 2$, pick the second column from $\left\{\xi_{1}, \xi_{2}\right\}$ (two choices); otherwise pick it from $\mathcal{X}_{q}\left(2^{1}-1=1\right.$ choice $)$.
- If $2^{q}-1 \geq c$, pick the $c$ th column from $\left\{\xi_{1}, \ldots, \xi_{c}\right\}$ (c choices);
otherwise pick it from $\mathcal{X}_{q}\left(2^{q}-1\right.$ choices $)$.
- If $2^{q}-1 \geq k=n-p$, pick the $k$ th column from $\left\{\xi_{1}, \ldots, \xi_{k}\right\}$ ( $k$ choices);
otherwise pick it from $\mathcal{X}_{q}\left(2^{q}-1\right.$ choices $)$.

## Some Timings for impossible requests

Times[s] from function FrF2 for attempting to block a suitable $(k+p)-p$ fraction into blocks of size 4 , while keeping a clique of size 4 clear

| $k$ | run size | $p=0$ | $p=1$ | $p=2$ | $p=3$ | $p=4$ | $p=5$ | $p=6$ | $p=7$ | $p=8$ |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
|  |  |  |  |  |  |  |  |  |  |  |
| 5 | 32 | 0.12 | 0.12 | 0.13 | 0.02 |  |  |  |  |  |
| 6 | 64 | 0.32 | 0.28 | 0.23 | 0.23 | 0.30 | 0.23 |  |  |  |
| 7 | 128 | 0.91 | 0.75 | 0.64 | 0.53 | 0.47 | 0.58 | 0.66 | 0.41 | 0.43 |
| 8 | 256 | 2.67 | 2.46 | 1.97 | 1.63 | 1.39 | 1.15 | 0.99 | 0.90 | 0.82 |
| 9 | 512 | 8.64 | 7.16 | 5.89 | 5.19 | 4.06 | 3.56 | 3.24 | 3.05 | 2.91 |
| 10 | 1024 | 28.17 | 23.89 | 18.81 | 15.27 | 12.50 | 10.34 | 8.75 | 7.70 | 6.84 |
| 11 | 2048 | 91.36 | 72.41 | 59.92 | 48.57 | 40.22 | 33.42 | 27.35 | 22.61 | 18.86 |
| 12 | 4096 | 287.98 | 252.67 | 206.85 | 165.66 | 131.00 | 110.97 | 92.20 | 78.42 | 68.66 |

## Back matter

> Full factorial 2-level designs

Blocking full factorials

Regular fractional factorial 2-level designs

Clear two-factor interactions

Back matter

## Limitations

- Quality criteria for blocked designs are ignored - best (MA) unblocked fraction with most clear 2fis is found.
- There are not enough catalogues for large fractions (and some are huge!).
- The need of a manual restart of the algorithm is a nuisance.
- Searches can take a long time.

## Concluding comments

- With Godolphin's (2021) approach, it became feasible to automate blocking with keeping a requirement set of 2 fis clear.
- The approach is generally good for small blocks, even without a special interest in clear 2 fis.
- For fractional factorial 2-level designs, play with FrF2 and contact me in case of questions etc.
- I am interested in application show cases.
